Compiler Design

Unit 3: SDD to SDT

Preet Kanwal

Department of Computer Science & Engineering

In this lecture, you will learn about -

- L-attributed SDD to SDT
- SDT Implementation
- S-attributed SDD to SDT (Postfix SDT)

Conversion of L-attributed SDD to SDT

Translation by traversing a parse tree

- Build parse tree and annotate.
- Build the parse tree, add actions and execute the actions in pre-order.

Conversion of L-attributed SDD to SDT

Translation by traversing a parse tree

- Build parse tree and annotate.
- Build the parse tree, add actions and execute the actions in pre-order.

Conversion of L-attributed SDD to SDT

Translation during parsing

- Use a RDP with a function for each non-terminal.
- Generate code on the fly, using a RDP.
- Implement an SDT in conjunction with an LL parser.
- Implement an SDT in conjunction with an LR parser.

Conversion of L-attributed SDD to SDT

- Place the computation of **inherited attributes** for a non-terminal **before** that non-terminal appears in the right hand side of the production.
- Place the computation of **synthesized attributes** at the **end** of production.

Evaluation of L-attributed SDD

- L-attributed SDDs can have both synthesized attributes and inherited attributes.

Rule to be followed for evaluation

- Place the semantic rule corresponding to the inherited attributes of the non-terminal before the non-terminal appears on the right hand side of the production.
- Place the semantic rule corresponding to the synthesized attributes of the non-terminal at the end of the production.

Conversion of L-attributed SDD

Example

Production	Semantic Rule
$T \rightarrow FT'$	$T'.ival = F.val; T.val = T'.val;$
$T \rightarrow *FT1'$	$T1'.ival = T.ival * F.val;$ $T'.val = T1'.val;$
$T' \rightarrow \lambda$	$T'.val = T'.ival;$
$F \rightarrow num$	$F.val = num.lexval$

Conversion of L-attributed SDD

Example (contd.)

$T \rightarrow F \{ T'.ival = F.val; \} T' \{ T.val = T'.val; \}$

$T' \rightarrow *F \{ T1'.ival = T'.ival * F.val; \} T1' \{ T'.val = T1'.val; \}$

$T' \rightarrow \lambda \{ T'.val = T'.ival; \}$

$F \rightarrow \text{num} \{ F.val = \text{num.lexval}; \}$

L-attributed SDD to SDT - Type Declarations

Production	Semantic Rule	Translation Scheme
$D \rightarrow T L$	$\{ L.in = T.type; \}$	$D \rightarrow T \{ L.in := T.type \} L$
$T \rightarrow \text{int}$	$\{ T.type = integer; \}$	$T \rightarrow \text{int} \{ T.type := 'integer' \}$
$T \rightarrow \text{real}$	$\{ T.type = float; \}$	$T \rightarrow \text{real} \{ T.type := 'real' \}$
$L \rightarrow L_1, id$	$\{ L_1.in = L.in; \}$ $\{ addType(id.entry, L.in); \}$	$L \rightarrow \{ L1.in := L.in \} L1, id$ $\{ addtype(id.entry, L.in) \}$
$L \rightarrow id$	$\{ addType(id.entry, L.in); \}$	$L \rightarrow id \{ addtype(id.entry, L.in) \}$

L-attributed SDD to SDT - Intermediate Code Generation

Convert the L-attributed SDD to generate intermediate code for If statement to SDT -

Production	Semantic Rule
$S \rightarrow \text{if}(C) S1$	$C.true = \text{new label}();$ $C.false = S.next;$ $S1.next =$ $S.next;$ $S.code = C.code \parallel \text{label}(C.true) \parallel S1.code$

L-attributed SDD to SDT

Translation Scheme -

$$S \rightarrow \text{if (} \left\{ \begin{array}{l} C.\text{true} = \text{new label ()}; \\ C.\text{false} = S.\text{next} \\ S1.\text{next} = S.\text{next} \end{array} \right\} C) S1 \left\{ \begin{array}{l} S.\text{code} = C.\text{code} \mid \mid \\ \text{label}(C.\text{true}) \mid \mid \\ S1.\text{code} \end{array} \right\}$$

L-attributed SDD to SDT

Convert the L-attributed SDD to generate intermediate code for while statement to SDT :

Production	Semantic Rule
$S \rightarrow \text{while } (C) S1$	$\begin{aligned} &begin = \text{new label}(); \\ &C.true = \text{new label}(); \\ &C.false = S.next \\ &S1.next = begin \\ &S.code = \text{label}(begin) \parallel C.code \parallel \text{label}(B.true) \parallel \\ &S1.code \parallel \text{gen('goto' label}(begin)); \end{aligned}$

L-attributed SDD to SDT

Translation Scheme -

$S \rightarrow \text{while } \left\{ \begin{array}{l} \text{begin} = \text{new label } (); \\ \text{C.true} = \text{new label } (); \\ \\ \text{C.false} = S.\text{next}; \\ S1.\text{next} = \text{begin}; \end{array} \right\}$

$\text{C) } S1 \left\{ \begin{array}{l} S.\text{code} = \text{label}(\text{begin}) \\ || \text{C.code} || \\ \text{label}(\text{C.true}) || \\ S1.\text{code} || \text{gen('goto' } \\ \text{label}(\text{begin})); \end{array} \right\}$

There are two ways to implement a SDT scheme :

- 1. After Parsing - Work with the output of Parser (Parse Tree)**
- 2. During Parsing**

SDT Implementation - After Parsing

- Ignoring the actions, parse the input and produce a parse tree as a result.
- Examine each interior node N.
- Add additional children to N for the actions.
- Perform a preorder traversal of the tree, and as soon as a node labelled by an action is visited, perform that action.

SDT Implementation - After Parsing

- Consider the following translation scheme.

$S \rightarrow ER$

$R \rightarrow *E \{ \text{print}("*"); \} R \mid \epsilon$

$E \rightarrow F + E \{ \text{print}("+"); \} \mid F$

$F \rightarrow (S) \mid \text{id} \{ \text{print}(\text{id.value}); \}$

Here **id** is a token that represents an integer and **id.value** represents the corresponding integer value.

For an input **2 * 3 + 4**, this translation scheme prints _____.

SDT - Infix to Postfix

Production	Semantic Rule
$E \rightarrow E1 + T$	
$E \rightarrow T$	
$T \rightarrow T1 * F$	
$T \rightarrow F$	
$F \rightarrow \text{num}$	
$F \rightarrow \text{id}$	

Production	Semantic Rule
$E \rightarrow E1 + T$	$E \rightarrow \{printf("+");\} E1 + T$
$E \rightarrow T$	$E \rightarrow T$
$T \rightarrow T1 * F$	$T \rightarrow \{printf("*");\} T1 * F$
$T \rightarrow F$	$T \rightarrow F$
$F \rightarrow num$	$F \rightarrow num \{printf("%d", num.lexval);\}$
$F \rightarrow id$	$F \rightarrow id \{printf("%d", id.lexval);\}$

Evaluation of S-Attributed Definitions

- Synthesized Attributes can be evaluated by a bottom-up parser as the input is being analyzed avoiding the construction of a dependency graph.
- The parser keeps the values of the synthesized attributes in its stack.
- Whenever a reduction $A \rightarrow \alpha$ is made, the attribute for A is computed from the attributes of α which appear on the stack.
- Thus, a translator for an S-Attributed Definition can be simply implemented by extending the stack of an LR-Parser.

Extending a Parser Stack

- Extra fields are added to the stack to hold the values of synthesized attributes.
- In the simple case of just one attribute per grammar symbol the stack has two fields - state and val.
- The current top of the stack is indicated by the pointer top.

- Synthesized attributes are computed just before each reduction :

- Before the reduction $A \rightarrow XYZ$ is made, the attribute for A is computed :

$A.a := f(s[top].val, s[top - 1].val, s[top - 2].val).$

state	val
Z	Z.x
Y	Y.x
X	X.x
...	...

Postfix SDT scheme for simple desk calculator

$E \rightarrow E1 + T \quad \{ \text{stack}[\text{top}-2].\text{val} = \text{stack}[\text{top}-2].\text{val} + \text{stack}[\text{top}].\text{val}; \text{top} = \text{top} - 2; \}$

$E \rightarrow T$

$T \rightarrow T1 * F \quad \{ \text{stack}[\text{top}-2].\text{val} = \text{stack}[\text{top}-2].\text{val} * \text{stack}[\text{top}].\text{val}; \text{top} = \text{top} - 2; \}$

$T \rightarrow F$

$F \rightarrow (E) \quad \{ \text{stack}[\text{top}-2].\text{val} = \text{stack}[\text{top}-1].\text{val}; \text{top} = \text{top} - 2; \}$

$F \rightarrow \text{digit}$

Implementing SDT Scheme during LR Parsing

- Introduce a **Marker Non-terminal** in place of each embedded action.

- There is one production for each Marker M,
 $M \rightarrow \lambda$

Example :

$A \rightarrow \text{alpha } \{a\} \text{ beta } \{b\}$

would convert to

$A \rightarrow \text{alpha } M \text{ beta } \{b\}$

$M \rightarrow \lambda \quad \{a\}$

Implementing SDT Scheme during LR Parsing

- For Example consider the following SDT scheme to generate Intermediate code :

$$P \rightarrow \{S.next = new label();\} S \{ P.code = S.code \mid \mid label(S.next); \}$$

$$S \rightarrow id = num ; \{ S.code = gen(id.name "=" num.lexval); \}$$

$$S \rightarrow while (\left\{ \begin{array}{l} \text{begin} = new label (); \\ C.true = new label (); \\ C.false = S.next; \end{array} \right\} C) \left\{ \begin{array}{l} S1.next = begin; \\ S1 \left\{ \begin{array}{l} S.code = label(begin) \mid \mid \\ C.code \mid \mid label(C.true) \\ \mid \mid S1.code \mid \mid \\ gen("goto" \\ label(begin)); \end{array} \right. \end{array} \right\}$$

$$C \rightarrow id_1 \text{ rel } id_2 ; \{ C.addr = new Temp(); \\ C.code = gen (C.addr "=" id1.name \text{ rel.op } id2.name) \\ \mid \mid gen ("if" C.addr "goto" label(C.true)) \mid \mid gen("goto" label(C.false)); \}$$

Implementing SDT Scheme during LR Parsing

Introducing a Marker Non Terminal for every embedded action...

$P \rightarrow X S \{ P.code = S.code \mid \mid label(S.next); \}$

$X \rightarrow \lambda \quad \{ S.next = new label(); \}$

$S \rightarrow id = num ; \{ S.code = gen(id.name "=" num.lexval); \}$

$S \rightarrow while (M C) N S \{ S.code = label(begin) \mid \mid C.code \mid \mid label(C.true) \mid \mid S1.code \mid \mid$
 $\quad \quad \quad gen("goto" label(begin)); \}$

$M \rightarrow \lambda \{ begin = new label (); C.true = new label (); C.false = S.next; \}$

$N \rightarrow \lambda \{ S1.next = begin; \}$

$C \rightarrow id_1 rel id_2 ; \{ C.addr = new Temp();$
 $\quad \quad \quad C.code = gen (C.addr "=" id1.name rel.op id2.name)$
 $\quad \quad \quad \mid \mid gen ("if" C.addr "goto" label(C.true))$
 $\quad \quad \quad \mid \mid gen("goto" label(C.false)); \}$

Implementing SDT scheme during LR Parsing

Parser Stack Structure

Stack record		
	<i>A</i>	<i>Synthesized attributes of A</i>
	Inherited attributes of A	

Note : We perform general style of bottom-up parsing - shift-reduce parsing. A - non terminal

Implementing SDT scheme during LR Parsing

$M \rightarrow \Lambda$ {s[top].begin = new label(); s[top].true = new label();
s[top].false = s[top-3].next;}

$N \rightarrow \Lambda$ {s[top].next = s[top-3].begin;}

$C \rightarrow id_1 \text{ rel } id_2$; { s[top-2].addr = new Temp();
s[top-2].code = gen(s[top].addr "=" s[top-2].name s[top-1].op s[top].name)
|| gen("if" s[top].addr "goto" label(s[top-3].true)
|| gen("goto" label(s[top-3].false); top = top - 2; }

Implementing SDT scheme during LR Parsing

Example 2 :

$$S \rightarrow \text{if (} \left\{ \begin{array}{l} C.\text{true} = \text{new label ()}; \\ C.\text{false} = S.\text{next}; \end{array} \right\} C) \left\{ S1.\text{next} = S.\text{next}; \right\} S1 \left\{ \begin{array}{l} S.\text{code} = C.\text{code} \mid \mid \\ \text{label}(C.\text{true}) \mid \mid S1.\text{code} \end{array} \right\}$$

Run over the input string `if(x>y) x= 5;` and provide all semantic actions in terms of stack operations.

Implementing SDT scheme during LR Parsing

Example 3 :

$T \rightarrow F \{ T'.ival = F.val; \} T' \{ T.val = T'.val; \}$

$T' \rightarrow *F \{ T1'.ival = T'.ival * F.val; \} T1' \{ T'.val = T1'.val; \}$

$T' \rightarrow \lambda \{ T'.val = T'.ival; \}$

$F \rightarrow \text{num} \{ F.val = \text{num.lexval}; \}$

Run over the input string $3*5$ and provide all semantic actions in terms of stack operations.
